#### PREFACE

This publication provides information pertaining to the IMP-16C DEBUGC Utility Program. The DEBUGC language, communications requirements and procedures, and control statements are described. The DEBUGC listing is presented as appendix A.

The material in this manual is for information purposes only and is subject to change without notice.

Copies of this publication and other National Semiconductor publications may be obtained from the sales offices listed on the back cover.

#### DEBUGC UTILITY PROGRAM

#### 1.0 INTRODUCTION

DEBUGC is a firmware program that supervises the operation of a user's program during checkout. The user has the facility to enter a set of commands to the DEBUGC program, through a Teletype keyboard, to which the DEBUGC program responds by performing the requested action and communicating data back to the user through the Teletype printer. DEBUGC provides the following facilities for testing and running the user's programs in the IMP-16C.

- Printing selected areas of memory in hexadecimal format.
- Modifying the contents of selected areas in memory.
- Modifying processor registers and the top word of the stack.
- Inserting instruction breakpoint halts.
- Initiating execution at any point in program.

The DEBUGC listing is given in appendix A.

#### 2.0 CONFIGURATION AND USAGE

The minimum system configuration needed is an IMP-16C, a control panel, and a Teletype. A simple Teletype interface circuit as described in the IMP-16 Application Manual, Supplement 1 (or IMP-16 Interfacing Guide), is also needed. DEBUGC is supplied as a set of two ROMs designed to be used with two CUTIL ROMs (IMP-16C Utilities program). In this mode of use, the CUTIL ROMs are inserted in the memory range  $FF00_{16}$  to  $FFFF_{16}$ , and DEBUGC occupies the range  $FE00_{16}$  through  $FEFF_{16}$ . DEBUGC uses location 0 and locations 2 through X'E of base page; these locations must not be altered by the user while DEBUGC is being used.

#### 2.1 DEBUGC LANGUAGE

The control statements which are used to command the operation of DEBUGC are confined within a set of rules which define the syntax (the format of control statements), and semantics (the meanings of the various symbols and characters comprising the control statement) of the language.

#### 2.1.2 Conventions Used in This Manual

The following notation is used, both in the general cases (in the command descriptions) and in the specific cases (in the examples):

- Mixed upper- and lower-case characters are used for comments and notes.
- Nonunderlined characters, numbers, and symbols, used in the examples, indicate computergenerated output from the Teletype printer. For example, memory contents appear as follows:

0100 7890 2413 0016

Underlined characters, numbers, and symbols, used in the examples indicate user-generated input at the Teletype keyboard. Two classes of statements are underlined, lower-case and upper-case as follows:

> Lower-case statements or statement parts represent the general case (to be further defined by the rules of syntax).

Upper-case statements or statement parts represent the exact (specific) form of the input required to be typed in.

For example: > T < address argument> (general case)

> > T <u>2345:2375</u> (specific case) > NOTE ADDRESS (specific case)

Circled upper-case characters represent operation of Teletype keyboard keys that do not generate a printed character.

CR represents the carriage return key.

LF represents the line feed key. For example:

#### 2.1.3 Syntax and Semantics

The basic elements of DEBUGC commands are defined below. In the formal (symbolic) descriptions of DEBUGC commands, the following symbols are used:

<a>> Specifies an element 'a' either of a command or of another element.

: := Means 'is defined as' and appears in a statement which defines the element to its left.

Indicates that one of the elements specified inside the braces must be included in the statement.

Indicates that the element(s) specified within the brackets are optional and need not be included in the command, unless desired.

#### 2.1.4 Syntax

The following meanings are assigned to the terms used in the general-case form of the statements:

<hexadecimal number>::= From one to four digits from the hexadecimal set (0, 1, 2, 3, 4, 5, 6, 7,

8, 9, A, B, C, D, E, F). Leading zeros may be omitted. If more than

four digits are entered, only the last four are used.

<value> : := A four-digit hexadecimal number used as the contents of a memory

location or the contents of a register. Consists of a 16-bit number.

<memory address>: := A four-digit hexadecimal number specifying a memory location.

Leading zeros may be omitted.

<memory address range>: := A memory address, followed by a colon (:), followed by a second

memory address.

For example: 3528:354A

The memory address to the left of the colon represents the low limit of the range; the address to the right of the colon represents the high limit of the range. If the upper limit of the range is smaller than the lower limit of the range, DEBUGC accepts only the lower number and performs the requested operation at that address.

<register address>

A register address may be selected from the set of the following:  $0,\ 1,\ 2,\ 3,\ 4,\ 5$ 

0 represents AC0

1 represents AC1

2 represents AC2

3 represents AC3

4 represents Flag Register

5 represents Top Word of Stack

<comment>

English language text, including letters and numbers, exactly as typed in.

#### 2.1.5 Semantics

All numbers input to DEBUGC may be either decoded as hexadecimal or used in the NOTE command in ASCII format. The following description explains the use of certain characters:

: (colon) Delimiter for a range argument. Signifies that all the locations from the first entry through the last are included in the range; that is, a:b signifies all the locations from a through b, including a and b.

, (comma) Delimiter of address and range arguments.

### 3.0 COMMUNICATIONS

The user can communicate with DEBUGC through a Teletype. Whenever DEBUGC takes control, it types the 'greater than' character (>) to indicate that it is ready to accept a command. The user then may type control statements to direct the operation of DEBUGC. All commands must be terminated by a carriage return CR or a line feed LF. To abort a command, the ALT MODE key may be pressed at any time before the LF or CR; the (?) symbol is printed and no further action occurs. Blanks have no significance and may be inserted anywhere; the null and rubout characters also are ignored. If DEBUGC detects an error in a command, it types a question mark (?) and prompts for a new command by typing the prompt character (>).

Control is returned to DEBUGC from a user's program by use of the HALT command. DEBUGC types the prompt (>) upon reentry. Control is transferred back to the user's program from DEBUGC by the GO (G) directive. Details pertaining to the HALT and GO directives are described under the descriptions of the commands.

#### 4.0 CONTROL STATEMENTS

A control statement consists of a single alphabetic character representing the command to be performed, followed by a parameter list of the arguments for the commanded operation; the arguments are separated by commas. The numeric fields in a parameter list must be in hexadecimal notation; leading zeros may be

omitted. Overflow is not checked; only the last four digits entered are used. This feature may be used to correct typing errors without retyping the whole line. Blank characters are ignored, as are the null and rubout characters. A statement must be terminated with a carriage return (CR) or a line feed (LF)

In the examples that follow, information which is input by the user is shown underlined. A summary of the commands and the statement format is listed in table 4-1.

Statement Format Command A <memory address>, <value> [, <value>...] ALTER or A, <value> [, <value> ...] G<memory address> GO H < memory address> HALT I<value>, <memory address range> INSERT L<register address>,<value>[,<value>...] LOAD REGISTER REGISTER TYPE T/<memory address> TYPE (<memory address range>)

Table 4-1. Summary of DEBUGC Commands

#### 4.1 TYPE

The contents of the specified locations are printed on the terminal in hexadecimal notation. For each line of the printout, the starting address is printed, followed by one to eight locations per line. The address for a new line is always a multiple of eight for consistency and ease of reading. The first line may contain fewer than eight locations if the starting address is not a multiple of eight. The final location referenced becomes the value of the current location (CL).

As information is transmitted to the Teletype, the Teletype is interrogated for input. If any character is detected, the output is terminated and the user is prompted for another DEBUGC command. This feature may be used for terminating an excessive or undesirable output.

The following example illustrates the use of the TYPE command. The first line following the prompt character (>) is input by the user; the following lines and the final prompt character are generated by DEBUGC and are output by the program:

#### 4.2 REGISTER TYPE

R

The contents of the four registers plus the flags and the top-of-stack are printed on the terminal in hexadecimal notation. The order to printout is as follows: ACO, AC1, AC2, AC3, FLAGS, TOP-OF-STACK. The following example illustrates the use of the REGISTER TYPE command. The user enters the character 'R', followed by a  $\bigcirc$ R. DEBUGC generates the second line and the following prompt character:

#### 4.3 ALTER

The ALTER command alters the contents of memory beginning at the address specified. Each subsequent value is stored in the next higher location. A null field (two commas with no intervening number) leaves the corresponding memory location unaltered. If the memory address (first) field is null (no number), alteration commences with the current location. The current location is the location following the last location altered. The following example illustrates use of the ALTER command. The TYPE commands are included to show the data change in the specified memory ranges. The characters on each line following the prompt character are input by the user; the tabulated data is generated by DEBUGC.

When the ALTER command is terminated with use of the (ALT MODE) key, the operation is aborted at the current value being entered. Typing the comma, following the entry of a value, causes the value to be stored in the specified location. If the last value before the (ALT MODE) is followed with a comma, it is used; if the value is not followed with a comma, the ALTER command is aborted before the value is used to alter the specified location. The (ALT MODE) does not abort the entire command.

For example:

#### 4.4 LOAD REGISTER

The LOAD REGISTER command works in exactly the same manner as the ALTER command, except that it is the value stored in a register that is changed rather than a value in main memory. Care must be taken to ensure that the parameter list of values does not extend beyond the register save area. The allowed register addresses are as follows:

0 AC0
1 AC1
2 AC2
3 AC3
4 STATUS FLAGS
5 TOP-OF-STACK

The following example is a sample of user input, specifying the LOAD REGISTER command:

The register values are stored in memory until the GO instruction is executed. The LOAD REGISTER command alters these saved values. The SELECT Flag may be examined in memory location 0008, using the TYPE command, and may be altered via the ALTER command. A value of 0 or 1 must be used.

#### 4.5 INSERT

The INSERT command may be used to insert a value in a selected memory location. The original word, in the selected location, and all subsequent words within the defined range are moved up one word; the new data word is then inserted in the first location of the range, which is the selected location. Care must be exercised when using this command to insert a word in a block of instructions because forward and backward address references will be changed within the particular program segment.

The range specification must contain two addresses. The data from the first location to the last location (inclusive) is moved up one; that is,  $(x + 1) \leftarrow (x)$ . The first address specified is then replaced with the hexadecimal number (value). The data in the location following the specified range will be lost.

The following example illustrates use of the INSERT command. The user enters the command following the prompt character. The TYPE command is included to display the contents of the specified range before and after the INSERT command is used.

#### 4.6 HALT

#### H <memory address>

The HALT command terminates control by the user's program at the location specified and returns control to DEBUGC. HALT causes the program to terminate just before the memory address specified in the command. The instruction is subsequently executed immediately after control is returned to the user's program by use of the GO command. The halt location must be in read/write memory; no halt occurs during execution if the location specified is in ROM.

The HALT command works by exchanging the instruction at the given location for a JMP (jump) to DEBUGC, saving the original instruction for later execution after the GO command. Only one HALT may by in use at a time; a subsequent HALT command resets the original location and sets a new breakpoint halt location. The HALT may be removed and no new HALT set by a HALT command with a zero address (H0).

A GO command following the HALT command is successfully executed only when the instruction at the HALT location and the instruction at the following location always are executed consecutively; or when the instruction is a base page or indexed jump (but not a PC-relative jump). Other PC-relative instructions do work, but the operand is always wrong (since the instruction is not actually executed in its original location).

#### 4.7 GO

#### G <memory address>

The GO command starts execution of the user's program at the location specified by the memory address operand of the GO statement or (by default when this operand field is not used) at the memory address of the last executed HALT command. However, if the last halt instruction was an HO command, removing

the active halt command, an error condition occurs when the GO command attempts to use this address (see HALT command, paragraph 4.6). DEBUGC flags this condition and returns to the command mode by typing a new prompt character (>). If when first turned on, prior to using any HALT commands, a GO command without a memory address operand is used, unpredictable results occur.

To avoid the situation where a jump to an unpredictable address may occur, it is suggested that the user first type in an H0 command to set the halt address to 0000. Thus an inadvertent GO command without an address will not cause the user's program to be destroyed in memory.

The four registers, the flags and the Select Flag all are restored when the GO command is given. The top location of the stack is saved and is also restored. The remaining locations in the stack are unaltered, but since DEBUGC does not save these locations of the stack, stack overflow may occur if the stack is more than half-full. Up to eight words in the bottom of the stack may be cleared during execution of DEBUGC.

The HALT and GO instructions may be used to step through a program one instruction (or a few) at a time.

For example, suppose the main program is as follows:

36	0040	4C00		LI	0,0
37	0041	2444		JSR	SUB
38	0042	0F80		PFLG	7
39	0043	0000		HALT	
40	0044	XXXX	SUBR:	xxxx	XXXX
$\mathbf{x}\mathbf{x}$	XXXX	XXXX		xxxx	XXXX
xx	XXXX	XXXX		xxxx	XXXX
		0020		RTS	

Single Stepping:

#### 4.8 NOTE

#### N <comment>

The NOTE command permits the user to comment his debugging. All text, up to the carriage return or line feed, is printed on the terminal. No other action is performed. The following are some examples of NOTE COMMENTS:

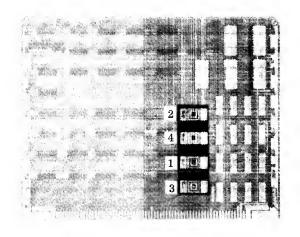

N \*\*\* INSERT INSTRUCTION \*\*\* CR N ALTMODE CAUSES ABORT CR NOTE THAT THE TTY PUNCH IS OFF CR

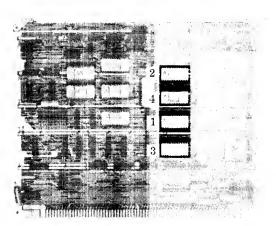

### 5.0 ROM LOCATIONS

Depending on which IMP-16 microprocessor is being used, the location of the ROMs containing DEBUGC and CUTIL are shown in figure 5-1.
